

CSCSE 689: Special Topics in Modern Algorithms for Data Science

Lecture 4

Samson Zhou

Today

- Sign up for LaTeX scribe note slots

- Receive and consider list of potential projects/groups

Future

- **Wednesday**: Discuss potential project groups
- **Friday**: Email me the members/group name

- **Future**: Set up meetings to discuss proposed projects

Last Time: Expected Value

- The expected value of a random variable X over Ω is:

$$E[X] = \sum_{x \in \Omega} \Pr[X = x] \cdot x$$

- The “average value of the random variable”
- Linearity of expectation: $E[X + Y] = E[X] + E[Y]$

Last Time: Markov's Inequality

- Let $X \geq 0$ be a non-negative random variable. Then for any $t > 0$:

$$\Pr[X \geq t \cdot \mathbb{E}[X]] \leq \frac{1}{t}$$

- Can rewrite as $\Pr[X \geq t] \leq \frac{\mathbb{E}[X]}{t}$

- “Bounding the deviation of a random variable in terms of its average”

Limitations of Markov's Inequality

- Let X be the outcome of a roll of a die. Then $E[X] = 3.5 = \frac{7}{2}$

$$\Pr[X \geq 6] = \Pr\left[X \geq \frac{12}{7} \cdot \frac{7}{2}\right] \leq \frac{7}{12} \approx 0.5833$$

- We know $\Pr[X \geq 6] = \frac{1}{6} \approx 0.167$

Moments

- For $p > 0$, the p -th moment of a random variable X over Ω is:

$$E[X^p] = \sum_{x \in \Omega} \Pr[X = x] \cdot x^p$$

Variance

- The variance of a random variable X over Ω is:

$$\text{Var}[X] = E[X^2] - (E[X])^2$$

- Can rewrite $\text{Var}[X] = E[(X - E[X])^2]$ since $E[E[X]] = E[X]$
- “How far numbers are from the average”

Variance

- The variance of a random variable X over Ω is:

$$\text{Var}[X] = E[X^2] - (E[X])^2$$

- Linearity of variance for *independent* random variables: $\text{Var}[X + Y] = \text{Var}[X] + \text{Var}[Y]$

Variance and Standard Deviation

- The variance of a random variable X over Ω is:

$$\sigma^2 = \text{Var}[X] = E[X^2] - (E[X])^2$$

- The standard deviation of a random variable X is σ , and measures how far apart the outcomes are
- Standard deviation is in the same unit as the data set

Variance

- Suppose X takes the value 1 with probability $\frac{1}{2}$ and takes the value -1 with probability $\frac{1}{2}$
- What is $E[X]$?
- What is $\text{Var}[X]$? What is $\text{std}(X)$?

Variance

- Suppose Y takes the value 100 with probability $\frac{1}{2}$ and takes the value -100 with probability $\frac{1}{2}$
- What is $E[Y]$?
- What is $\text{Var}[Y]$? What is $\text{std}(Y)$?

Markov's Inequality

- Let $X \geq 0$ be a non-negative random variable. Then for any $t > 0$:

$$\Pr[X \geq t \cdot \mathbb{E}[X]] \leq \frac{1}{t}$$

- Can rewrite as $\Pr[X \geq t] \leq \frac{\mathbb{E}[X]}{t}$

Markov's Inequality

- Let $X \geq 0$ be a non-negative random variable. Then for any $t > 0$:

$$\Pr[X \geq t \cdot \mathbb{E}[X]] \leq \frac{1}{t}$$

- Can rewrite as $\Pr[X \geq t] \leq \frac{\mathbb{E}[X]}{t}$
- We have $\Pr[|X| \geq t] = \Pr[X^2 \geq t^2]$

Using Markov's Inequality

- We have $\Pr[|X| \geq t] = \Pr[X^2 \geq t^2]$

$$\Pr[|X| \geq t] = \Pr[X^2 \geq t^2] \leq \frac{E[X^2]}{t^2}$$

- Plug in $X - E[X]$ for X

$$\Pr[|X - E[X]| \geq t] \leq \frac{E[(X - E[X])^2]}{t^2}$$

Toward Chebyshev's Inequality

$$\Pr[|X - E[X]| \geq t] \leq \frac{E[(X - E[X])^2]}{t^2}$$

Chebyshev's Inequality

$$\Pr[|X - E[X]| \geq t] \leq \frac{E[(X - E[X])^2]}{t^2}$$

- Recall that $\text{Var}[X] = E[X^2] - (E[X])^2 = E[(X - E[X])^2]$
- $\Pr[|X - E[X]| \geq t] \leq \frac{\text{Var}[X]}{t^2}$

Chebyshev's Inequality

- Let X be a random variable with expected value $\mu := E[X]$ and variance $\sigma^2 := \text{Var}[X]$

- $\Pr[|X - E[X]| \geq t] \leq \frac{\text{Var}[X]}{t^2}$ becomes $\Pr[|X - E[X]| \geq t] \leq \frac{\sigma^2}{t^2}$

$$\Pr[|X - \mu| \geq k\sigma] \leq \frac{1}{k^2}$$

- “Bounding the deviation of a random variable in terms of its variance”

Chebyshev's Inequality

- Let X be a random variable with expected value $\mu := E[X]$ and variance $\sigma^2 := \text{Var}[X]$

$$\Pr[|X - \mu| \geq k\sigma] \leq \frac{1}{k^2}$$

- Do not require assumptions about X

Chebyshev's Inequality

- Let X be the outcome of a roll of a die. Then $E[X] = 3.5 = \frac{7}{2}$ and $\text{Var}[X] = \frac{35}{12} \approx 2.92$ so $\text{std}(X) \approx 1.71$

$$\begin{aligned}\Pr[X \geq 6] &= \Pr[X - 3.5 \geq 2.5] \\ &= \Pr[X - 3.5 \geq 1.41 \cdot 1.71] \\ &\leq \frac{1}{1.41^2} \approx 0.4667\end{aligned}$$

- Recall that Markov's inequality bounded this **0.5833**

Law of Large Numbers

- Let X_1, \dots, X_n be random variables that are independent identically distributed (i.i.d.) with mean μ and variance σ^2
- Consider the sample average $X = \frac{1}{n} \sum_i X_i$. How does it compare to μ ?
- $\text{Var}[X] = \frac{1}{n^2} \sum_i \text{Var}[X_i] = \frac{\sigma^2}{n}$
- By Chebyshev's inequality, $\Pr[|S - \mu| \geq t] \leq \frac{\sigma^2}{nt}$

Law of Large Numbers

- By Chebyshev's inequality, $\Pr[|S - \mu| \geq t] \leq \frac{\sigma^2}{nt}$
- **Law of Large Numbers:** The sample average will always concentrate to the mean, given enough samples
